In many insects, antennal sensory neurons are specialized for encoding olfactory signals. They express odorant receptors which mediate olfactory detection. Additionally, they are innervated by olfactory neurons, which receive multimodal sensory input from several antennal sensilla, including the sensillum lymphaticum, which receives sensory input from the antennae in close proximity to the antennae (proximal antennal contact). We assessed the importance of this multimodal antennal input by comparing the odor responses of large numbers of sensory neurons between antennae in close physical proximity and on opposite sides of the head. The olfactory processing of antennal olfactory stimuli was found to be stronger in antennae on the same side of the head and stronger in antennae in close proximity than in antennae on opposite sides. The intensity of odor-evoked responses and odor discrimination behavior was also increased in the latter compared to the former situation. However, this gain in olfactory encoding was not sufficient to suggest that proximal antennal contact is used for sensory integration or for long-distance communication.
